

# Enhanced Delta Smelt Monitoring

## Preliminary Analysis

### Phase 1 Sampling

**DRAFT**

U.S. Fish and Wildlife Service

January 12, 2018

## Overview

Beginning December 2017, the Enhanced Delta Smelt Monitoring (EDSM) program started its Phase 1 sampling program for adult delta smelt. The Bay-Delta has been divided into ten geographic strata (shown in figures below). Sampling locations are generated using a generalized random-tessellation stratified (GRTS) design [1] with stratification and equal probability sampling. Trawling gear similar to that used in the California Department of Fish and Wildlife's [Spring Kodiak Trawl Survey](#) is used to conduct multiple tows per location.

Everything presented here is preliminary and subject to correction, revision, and improvement. The following points should be taken into consideration when interpreting the results:

1. Delta smelt captured outside of the live box or cod end of the net could not be assigned to a specific tow and were excluded from this analysis. These fish are included in the daily catch summary and are indicated by a Gear Condition Code of 9. Delta smelt captured in highly impaired samples, e.g., samples with large net blockages of debris or vegetation, were also excluded from this analysis. These fish are included in the daily catch summary and are indicated by a Gear Condition Code of 3.
2. The **Week** designations used here were defined out of convenience and are subject to change.
3. Current sampling is limited to areas of the Bay-Delta with a depth of at least 8 feet at mean tide. The abundance estimation method used here assumes that the density of fish in unsampled areas (i.e., those with depth less than 8 feet) is the same as in sampled areas (i.e., those with depth greater than or equal to 8 feet).
4. The methods of analysis used here remain in development.

## Change Log

Report date December 18, 2017:

- New estimates of water volumes between 0.5-m and 4.5-m depth are being used to estimate abundance; these are shown in a table at the end of this report. Previous reports used estimates of volume between 0 m and 4 m depth.
- The stratification used here is similar but not identical to the stratification used in previous phases. Of particular note is the separation of Cache Slough/Liberty Island from the Sacramento Deep Water Ship Channel and the separation of Suisun Marsh from Suisun Bay.
- We are considering alternative stratification and sample allocation schemes that would increase the probability of catching delta smelt. This could mean, for example, combining areas expected to have low densities so we can increase the number of sampling locations in areas expected to have higher densities.

Report date December 22, 2017:

- Sampling took place Monday December 18<sup>th</sup> through Friday December 22<sup>nd</sup>. Data collected on the 22<sup>nd</sup> will be included in the next report.

Report date December 29, 2017:

- Sampling took place Tuesday December 26<sup>th</sup> through Friday December 29<sup>th</sup>. Data collected on the 29<sup>th</sup> will be included in the next report.
- Data collected on December 22<sup>nd</sup> have been included in this report.

Report date January 5, 2018:

- During the week of January 1, 2018, sampling took place between Tuesday January 2<sup>nd</sup> and Friday January 5<sup>th</sup>. Data collected on the 5<sup>th</sup> will be included in the next report.
- Data collected on December 29<sup>th</sup> have been included in this report.

Report date January 12, 2018:

- Data collected on January 5<sup>th</sup> have been included in this report.

## Results

Table 1: Delta smelt catch summary and abundance estimates by week. An asterisk (\*) is used to emphasize weeks when no delta smelt were caught and a dash (-) is used to indicate that sampling did not occur or that a quantity could not be calculated. In order to avoid confusion, weekly totals are only calculated when sampling has occurred in every stratum. Sample volumes are in cubic meters.
